13. ABSTRACT *(Maximum 200 words)*

Object-oriented relationships, such as inheritance and covering can not be readily incorporated in classic data models. This thesis addresses this problem by the design and implementation of an object-oriented data model (O-ODM), that incorporates the object-oriented paradigm.

A Multimodel and Multilingual Database System called M^2DBS has been developed at the Naval Postgraduate School. This system incorporates the classic database data models along with a recently developed object-oriented data model (O-ODM). The problem addressed by this work is to design a new object-oriented data manipulation language (O-ODML) for the O-ODM. The approach is to develop and construct an O-ODML Compiler. Then assimilate the compiler with the Kernel Mapping System (KMS) of the M^2DBS.

The result of this thesis is a compiler for the O-ODML of the O-ODM. This O-ODML compiler takes an O-ODM query converts it into a low level intermediate language before translating it into a format that the Real Time Monitor can execute on the M^2DBS

ABSTRACT

Object-oriented relationships, such as inheritance and covering can not be readily incorporated in classic data models. This thesis addresses this problem by the design and implementation of an object-oriented data model (O-ODM), that incorporates the object-oriented paradigm.

A Multimodel and Multilingual Database System called M^2DBS has been developed at the Naval Postgraduate School. This system incorporates the classic database data models along with a recently developed object-oriented data model (O-ODM). The problem addressed by this work is to design a new object-oriented data manipulation language (O-ODML) for the O-ODM. The approach is to develop and construct an O-ODML Compiler. Then assimilate the compiler with the Kernel Mapping System (KMS) of the M^2DBS.

The result of this thesis is a compiler for the O-ODML of the O-ODM. This O-ODML compiler takes an O-ODM query converts it into a low level intermediate language before translating it into a format that the Real Time Monitor can execute on the M^2DBS.

I. INTRODUCTION

A.   BACKGROUD

The value of data in today's information society requires data to be readily accessible. Furthermore, if data are stored in separate systems, they must be shared among these systems. If data cannot be easily shared among systems due to database design incompatibilities, the cost of database accesses and manipulations increases rapidly. These problems are more prevalent in large and long-standing organizations such as the Department of Defense. The proliferation of database systems and the heterogeneity of various databases have led to a multiplicity of database work, a redundancy of database storage, and a conglomeration of database systems which do not have the ability to readily share data.

Especially with today's fiscal constraints, the Department of Defense must be able to consolidate their resources in man, machine and software in order to save funds and increase productivity. Several solutions have been proposed to solve this problem such as:

- A single and massive conversion to a single database and a single database system
- Maintaining the original databases and database systems and implementing the translation software between any two databases and their systems
- A hybrid of the above two solutions.

All of these solutions suffer from some shortcomings. The first solution would require that all data be stored in a single database design. This would require that all the operators learn a new database system thereby increasing the cost of training operators. Further, the particular database design may not be well suited for storing and manipulating the data in question. In a diverse organization such as the Department of Defense, a single database design for all the diverse databases is not a viable option. The second solution would require the translation software between every pair of heterogeneous databases and their transactions in the organization. For a small number of heterogeneous databases and

systems, this is a feasible solution. When the number, n, of databases and database systems is large then the number of different translation software increases at a rate of $O(n^2)$, i.e. in the order of n^2. Therefore, the second solution becomes prohibitively costly. A more reasonable solution would convert all the data to a simple database design while allowing the original users to view their data in their original designs and to process the database with their original transactions. This solution is being explored in the Multimodel / Multilingual Database System M^2DBS. [Ref. 1] M^2DBS contains all the model / language interfaces for various pairs of the data models and data languages are supported on a kernel database system, known as the attribute-based database system.

B.   MOTIVATION

The overall goal for this project is to construct an Object-Oriented Interface on the Attribute-Based Database System (ABDS). The construction of this interface is to specifically allow for abstract object-oriented concepts such as objects, inheritance, classes and covering. The data definition language (DDL) directly incorporates these concepts. [Ref 2 and 3.] The interface is to contain a wide range of querying and manipulation capabilities. [Ref. 4] This thesis is to design and implement a compiler to translate Object-oriented queries and manipulations into equivalent ABDS queries and manipulations.

The compilation and translation of object-oriented queries and manipulations into ABDS queries and manipulations involved several steps. First, each query or manipulation must be scanned in order to identify its tokens. To produce the scanner, we used the tool LEX. As the scanner identifies the tokens a parser is needed to check the syntactic and semantic correctness of the query or manipulation. The tool YACC is used to produce the parser which accepts all the tokens and completes the parsing. Next, an intermediate language is developed to simplify the translation process. Finally, there is the query constructor which reads the intermediate-language table, the data dictionary, and the symbol table and writes the actual ABDS queries or statements. This final part of the compiler constitutes the bulk of the work, due to the limited functionality of the existing

2

ABDS data manipulation language compared to the relatively high level of functionality found in the Object-oriented data manipulation language (O-ODML). Since data being queried or manipulated are not accessible to the compiler, a method of translating individual lines and even parts of each line, must be developed to accommodate for the differences in data structures and language syntax of the two systems. Once the query or manipulation statement is converted and constructed, it is then passed to the real time monitor (RTM) [Ref. 5] for its execution.

C.   THESIS ORGANIZATION

This thesis is organized in four more chapters and twelve appendicies. In Chapter II we present the object-oriented constructs and the attribute based constructs that are relevant to the thesis. Since the complete definition of these constructs are the work of other thesis, for an in depth review of the constructs you should refer to the those documents. In addition, this chapter points out the conflicting nature of the two models. Chapter III introduces the reasons for choosing LEX and YACC to serve as development tools for the scanner and parser. Additionally, the manner of incorporating the symbol table and intermediate language table and the implementation of the scanner and lexer into the query constructor is also discussed in this chapter. In Chapter IV the query constructor and the general steps of it's algorithm are presented. Additionally, the real time monitor and the pseudocode which controls its operation are introduced. Also, in this chapter a sample query is translated. In Chapter V we make concluding remarks, state accomplishments and limitations.

The appendicies contain the in depth explanation of all aspects of the thesis. Throughout the work preparing for this thesis a series of documents were prepared to aid in the final writing of the thesis. Virtually every paragraph will refer to the appendices to amplify the text given in the thesis. Appendix A is the header file that contains the constructs of symbol table. Appendix B contains the definitions of the DML tokens and the C code that creates the symbol table. Appendix C contains the definitions of the DML

grammer and the calls to the functions of the intermediate language table main file. Appendix D is the rules that explain how to fill in the intermediate language table. Appendix E is the intermediate language table header file which contains the constructs and names of the functions used in building the table. Appendix F is the intermediate language table implementation file. Appendix G is the query constructor header file. Appendix H is the query constructor implementation file. Appendix I is the DML compiler main file which serves as the main file for the entire program. Appendix J is the instruction manual for the DML compiler. Appendix K is the translation algorithm for the conversion and construction process in the query constructor. And finally the pseudocode is defined in Appendix L.

II. OBJECT-ORIENTED AND ATTRIBUTE BASED CONSTRUCTS

A.   OBJECT-ORIENTED CONSTRUCTS

The DDL developed for the object-oriented data model (O-ODM) contains the following object-oriented constructs: objects, object identifiers, object classes, inheritance, covering and methods. For a complete description of these constructs and their scope refer to [Ref. 2], [Ref. 3] and [Ref. 4].

$$\begin{aligned}
&\textbf{Class } \textit{Class\_name } \{\\
&\quad \textit{attribute\_type} \quad \textit{attribute\_name}_1;\\
\\
&\quad \textit{attribute\_type} \quad \textit{attribute\_name}_x;\\
&\quad \textit{return\_type} \quad \textit{method\_name}_1;\\
\\
&\quad \textit{return\_type} \quad \textit{method\_name}_y;\\
&\};
\end{aligned}$$

Figure 1. Generic Object

The genric structure of an O-ODDL object class is shown in Figure 1. This generic example does not demonstrate the flexibilty and power of the object-oriented paradigm in modeling a data base. Figure 2, shows some of the object classes of the Faculty student (FACTSTU) database in which inherit, cover, set_of, and inverse_of relationships are displayed. By examining Figure 2, and comparing it with the reprenstation, of the FACTSU database, displayed in Figure 3, the flexibility of the O-ODM should be apparent.

Operations performed by the DML on the data demonstrate great flexibilty and power as well. The operations do require that the end user understand the object-oriented

5

paradigm, but gives the user a more rational view of the data. The complete description of the DML can be found in [Ref. 4].

```
class Name{                          class Address{
  char_string  fname;                  char_string  street;
  char         mi;                     char_string  city;
  char_string  lname;                  char         state[2];
};                                     char_string  zipcode;
                                     };

class Person{                        class Faculty : inherit Person{
  Name     pname;                      char_string    dept;
  Address  paddress;                   set_of Course  teaches;
  char     sex;                      };
}

class Student : inherit Person{      class Course{
  char_string    student_no;           char_string       cname;
  char_string    major;                char_string       cse_no;
  set_of Course  schedule;             char_string       sec_no;
};                                     Faculty           instructor;
                                       inverse_of Student.schedule  roster;
                                     };

class Team : cover Student{          class Civ_Fac : inherit Faculty{
  char_string    prjname;              char_string             title;
  set_of Civ_Fac advisor;              inverse_of Team.advisor  advises;
};                                   };
```

Figure 2. Sample Classes from the Faculty Student Database

B.   ATTRIBUTE-BASED CONSTRUCTS

The basic building block of the Attribute Based Data Model (ABDM) is the attribute-value pair. The attribute defines the qualities of the value. A set of these attribute

6
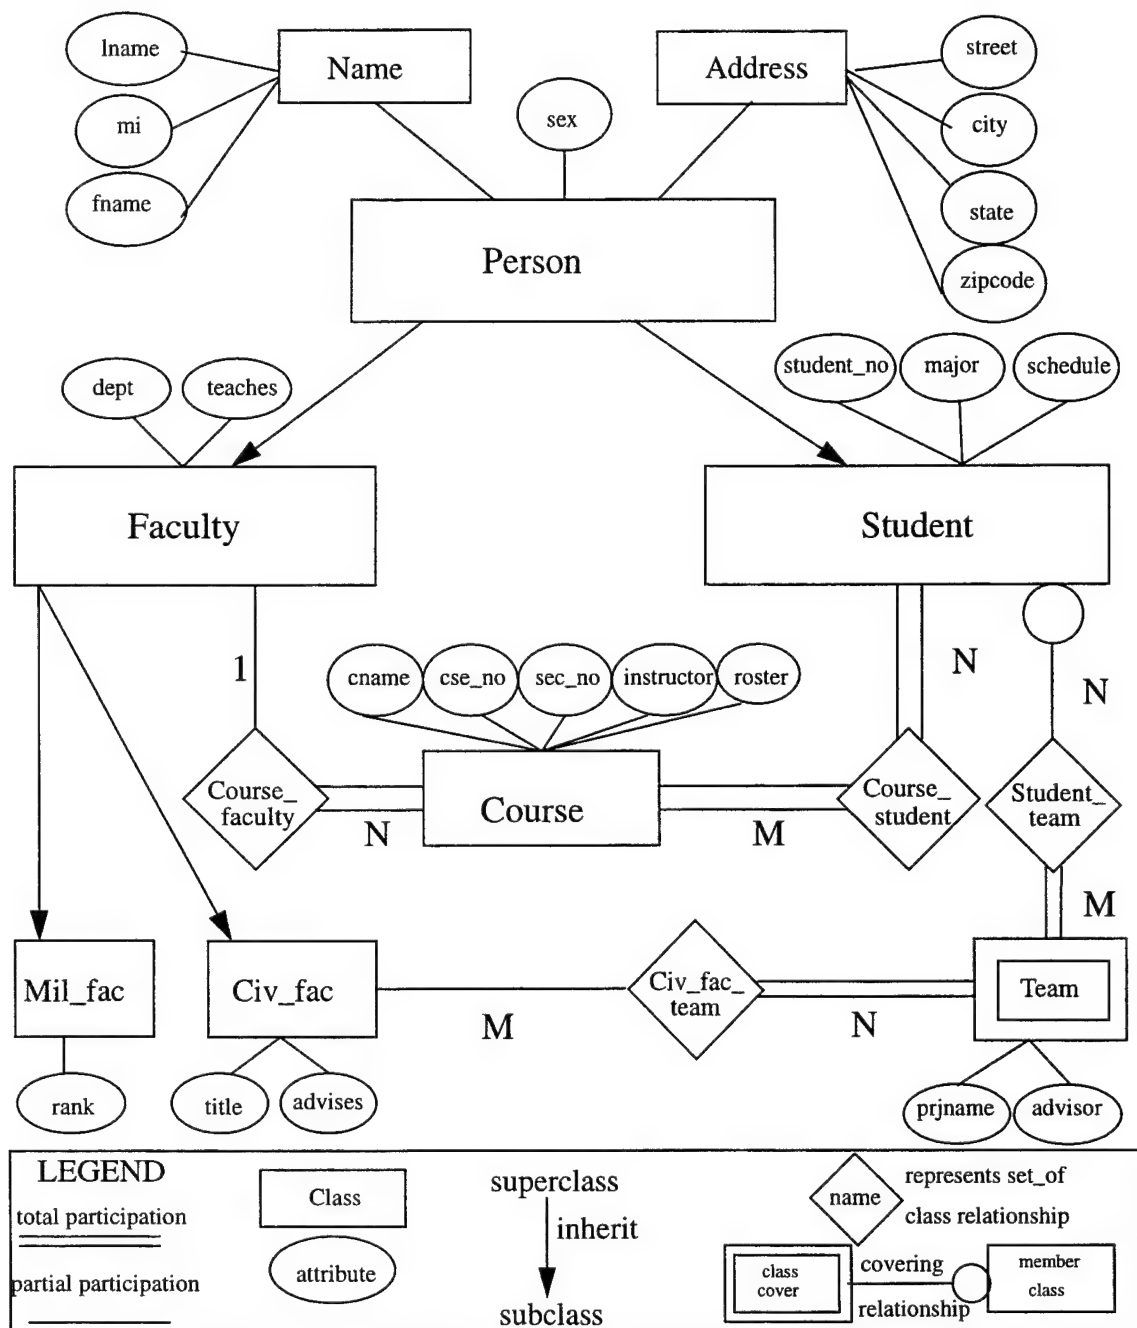

Figure 3. Relatioinship Diagram of the Faculty Student Database

value pairs defines a record, and the records are stored in templates. For a complete description of the ABDM and the available ABDS operations see [Ref. 1].

C. CONFLICTING NATURE OF THE O-ODM AND ABDM

When writing a search statement for the ABDS the user has understood logical ands in the operation. What is not available is "or" statements. Thus requiring searching the same template twice to accomplish what a single O-ODM query can do in a single simple search.

The end user in an object-oriented database when conducting searches, does not have to insure that the attributes he is referring to are directly in the class being queried. As long as dot notation is used to give a path expression signifying a relationship or inheritance with another class. The classic data models require that a search operation work on only one schema or table at a time thus requiring multiple searches with set operations to accomplish the task of one object-oriented search. The ABDS, like conventional models can only search one template at a time; moreover, unlike conventional models it presently can only execute a single operation without passing data between consecutive operations nor are set operations available.

The six operations available on the ABDS can not pass data from one search to another with the exception of the retrieve common operation. However, the retrieve common operation is very limited in its application since it can only pass information between two retrieves and not the remaining operations. This problem is significant in that a query involving multiple templates could not be executed unless the user incrementally queried the ABDS and then manually reentered the answers from the previous retrieve as the argument for the next operation. In other words if the first operation returned 25 answers then the user would have to enter each answer as an argument for the next operation 25 separate times. This presents a significant obstacle in translating a query since the O-ODM contains inheritance, cover, set_of, and inverse_of relations which cause a

single O-ODM query to automatically require multiple retrieve statements in the translation into ABDS queries. Due to limited resources specifically time the solution to this problem was to create a pseudocode [see Appendix L] and a real time monitor (RTM) [refer to Ref. 5] that could interpret the pseudocode and execute the queries incrementally.

III. THE COMPILER

A.   CHOOSING A SCANNER AND PARSER

Since the task was to build a compiler to translate Object-oriented queries into their Attribute-based equivalent, a compiler was definitely needed. Several problems were considered in deciding the course of action to take. First and foremost was the complexity and magnitude of the scanner and parser. Since the data manipulation language (dml) contained only 59 tokens a scanner would not have been too difficult to build, without the aid of a software tool. However, the dml consisted of over 84 production rules which in itself presented a major challenge in defining, without knowing if the rules were flawed. Additionally the problem of compatibility between the scanner and parser was considered. The probability of developing incompatible software or software that required significant modification in order to communicate was too great in choosing specific scanners and parsers. For these reasons the software tools of LEX and YACC together were used to produce the scanner and parser software. These tools were the logical choice for this task since both tools simplify the task of building a compiler, are guaranteed to be compatible and aid in catching errors in the token definitions and production rules.

B.   LEX

LEX is a software tool that allows the user to input token descriptions and then produces the code for the scanner, see [Ref. 6]. The token descriptions are input into LEX and it produces the file *lex.yy.c* which later is compiled with the output of YACC. Additionally, LEX allows the user to chose to execute a routine written in C code, on identification of a token. This code maybe added to the definitions given in the input file.

1. The Symbol Table

The creation of a symbol table was required to maintain a record of each identifier (variable) named in an object oriented query. The information stored in the symbol table is the name, the type and the class name of each variable. The name of each variable is simply the character combination chosen by the user to represent some value. The type of each

11

variable requires a little explanation. Since the object-oriented paradigm refers to objects as the building block of data structures, a logical choice for keys in the OODM would be object identifiers (OID). In order to simplify operations in both data models, it was decided that only OID's would be passed between operations until the final query, at which time the users desired manipulations would be executed. Because of this approach only two types of variables are relevant in this object-oriented model: object references (obj_ref) and object sets (obj_set). An obj_ref is simply a variable which can contain only one OID. While an obj_set is a variable that contains a set of variables which can be zero or many OID's.

C.   YACC

YACC is a software tool that allows the user to input a grammar and then produces the code for the parser, see [Ref. 7]. The grammar, also referred to as production rules, is input into YACC and the tokens identified in the LEX specification file must also be identified in the YACC specification file. When the specification file is input into YACC, it generate the C source file *y.tab.c* and *y.tab.h*. It is these two files that are compiled with the LEX output to create the compiler. Similar to LEX, YACC also allows the user to input C code and execute routines upon identification of a production rule.

1. The Intermediate Language Table

The purpose for the intermediate language table was to provide a structure to break down O-ODM queries and store them in a common format to allow for simplification of the translation of a query into the ABDS format. Rules were implemented to fill the intermediate language table according to the operations found in the O-ODM query, see Appendix D.

D.   IMPLEMENTATION

In this section, we will discuss the implementation of the scanner and parser in the compilation process. Figure 4, shows how LEX and YACC tie in with the compiler model.

For further information on the use of LEX and YACC see [Ref. 8] . For the O-ODDL compiler implementation of LEX and YACC see [Ref. 2].
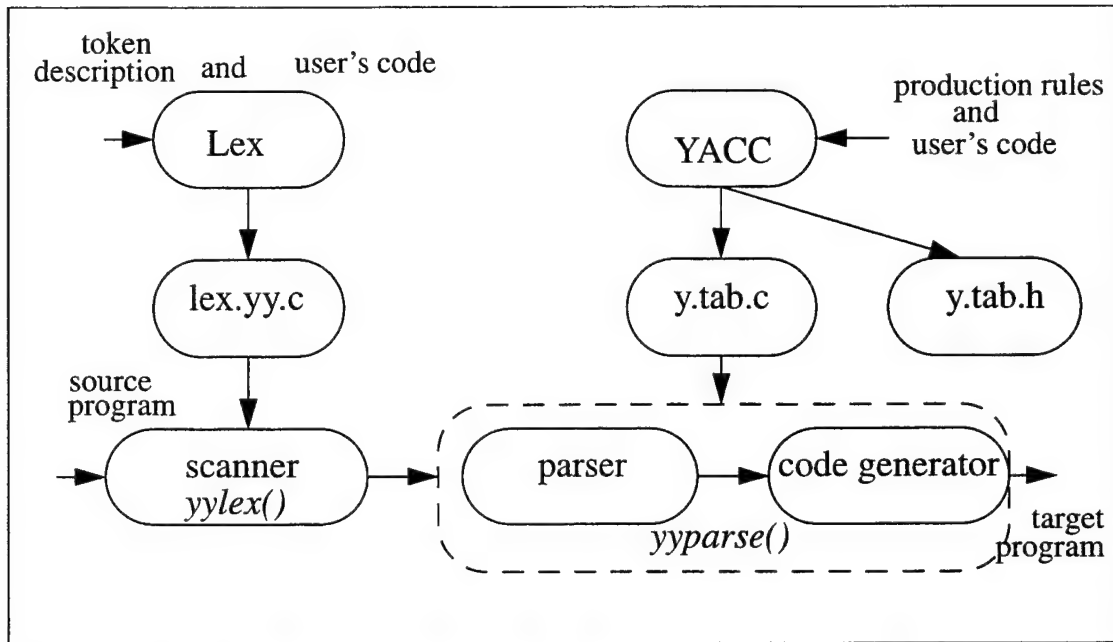

Figure 4. Scanner and Parser Implementation

1. The Scanner

The implementation of the scanner in the compilation process is as a subroutine called by the parser. The scanner takes an arbitrary input stream and tokenizes it, i.e., divides it up into lexical tokens. This tokenized output is then used as the input for the parser generated by YACC. The LEX specification file *dml_lex.l* was written in order to create a set of patterns which the scanner matches against the input see Appendix B. A special C routine named *symtablook()* was also embedded in the specification file to construct the symbol table during the scanning process. Lex itself does not produce an executable program; instead it translates the lex specification into a C source file named *lex.yy.c*. This file contains a C routine called *yylex()* which is a scanner. The executable scanner routine is produced by compiling *lex.yy.c* and linking it with the lex library -ll.

The primary task of the scanner is to recognize the tokens specified in the lex specification. The YACC parser calls *yylex()* to run the scanner. If the scanner encounters an unspecified token while scanning an input query, it gracefully terminates with an invalid token error, otherwise it sends all valid tokens to the parser.

In order to construct the symbol table, the scanner sets a flag for each type of declaration and upon reading the associated variable, it calls the embedded C routine *symtablook()* to construct the symbol table.

2. The Parser

The implementation of the parser in the compilation process is as a subroutine called by the main program of O-ODML compiler. Refer to the Appendix J for a complete discussion of this main program and its interface with the M^2DBS. The YACC specification file *dml_yacc.y* contains the specified tokens in the LEX specification file, the production rules and the embedded C routines to construct the intermediate table see Appendix C. YACC takes this specification file and generates the files named *y.tab.h* and y.tab.c. The executable parser subroutine *yyparse()* is produced as a result of compiling the source file *y.tab.c* with a regular C compiler.

When the parser routine y*yparse()* is called by the main program, this routine calls *yylex()* to tokenize the input query. The scanner then reads in the input of characters, until it finds a token of interest to the parser. The parser tries to find a list of tokens which matches a production rule provided in the YACC specification file. When the parser is done with the parsing process, either it outputs a "successfully parsed message" and calls the query constructor or it terminates gracefully with an error message including the corresponding line number.

In order to construct the intermediate table, the parser traces specific sequences of tokens in the production rules while it is scanning the input query. As soon as the parser has enough tokens to recognize a structure for the intermediate language table then it calls the

related C routine defined in the file *dml_yacc.y* thus initiating the intermediate language table construction process.

IV. THE QUERY CONSTRUCTOR

A.   GENERATING THE ATTRIBUTE BASED QUERY

The main program of the O-ODML compiler is inside the file *dml_compiler.c* [Appendix I], initiates the call to the parser, which is really how the compilation and translation process is commenced. Once the scanner and parser have completed the symbol table and intermediate language table respectively, the parser calls the function *query_constructor()* in the file *dml_comp.c* [Appendix H] (from this point on will be referred to as the query constructor) which actually does the translating of the queries. Prior to commencing the job of translating the queries the function *createDict()* accomplishes the task of converting the data dictionary file from a text format to a linked list format to simplify the search algorithm for the data dictionary. The query constructor then enters a switch statement (branch statement) in which it reads in the operation block of the intermediate language table and chooses the appropriate function call to convert that operation and its related arguments into an equivalent query. During this conversion the query constructor verifies the declaration of the variables used, to insure the correct type and class name are used. The type checking is accomplished by reading the symbol table. The next phase of the query constructor is to actually construct the ABDS query. This is where the pseudocode and ABDS manipulation langage merge to create a file that is read by the RTM and executed.

B.   READING THE INTERMEDIATE LANGUAGE TABLE

Since the intermediate language table is stored in a linked list of records (struct in C), see Appendix E, the method for locating and extracting information is through the use of pointers, loops and conditional statements. Each record in the linked list contains the row number of the table, the operation to be completed, up to two arguments to be used in the operation, and a result block which may contain a variable to be used in the conversion of the query. The operation indicates which function from the file *dml_comp.c*, see Appendix

H, will control the translation of that particular part of the query. The functions operate in two specific steps, the actual conversion phase which involves reading the data dictionary, and the construction phase which builds the operation with known arguments in the ABDS format. The construction phase is fairly self explanatory, but the conversion phase is more complex. Since attributes in the O-ODM can contain dot notation the location of an attribute in the ABDS may not exist in the same class as that of the attributes originally selected in the query. Since the ABDS can search only one template at a time, there exists the requirement to identify within which template the specified attributes are located. This requirement can only be satisfied by reading the data dictionary and extracting the true location (path expression) of the specified attribute.

C.   READING THE DATA DICTIONARY

Since the data dictionary is converted from a text file to linked list, the job of searching for specific data was generalized into functions which could be used over again. The first argument to be presented to the dictionary must always be a class name. Since O-ODM queries requires a classname for the desired return type, this is the argument used to enter the data dictionary. The function in_dictionary() takes the argument of the class name and searches the data dictionary for a template with that name and sets the current attribute pointer to the first attribute of that class. The next argument to be presented to the data dictionary is an attribute name. The function in_class() takes the argument of an attribute name and checks to see if that name exists within the current class and sets the pointer to it if found. The next check is to see if the contents of the relationship type column (rel_type) is empty indicating a primitive attribute. Then the construct call for this operation can be made. If the contents of the rel_type column is the string "store", indicating a "set_of" or "inverse_of" relationship, then a check of the attribute type (attr_type) column is made. If the type in the attr_type is a "set_of" then the search starts over in the class that is indicated in the reference table (ref_table) column. If the type in the attr_type column is an "inverse_of" then the contents of the ref_table column must be tokenized in order to

18

continue the search. Another possibility for the contents of the rel_type column is the string "ref" or "cover", if either these two are found then the search simply continues in the class indicated in the ref_table column. If the function in_class() does not find the attribute, it possibly still is related to the current class by way of the inheritance relationship. In that case a function to search for this relationship exist within dml_comp.c see Appendix H. For further explanation as to how the search of data in the data dictionary is accomplished see the convert functions in Appendix F or the algorithm in Appendix K.

D.   READING THE SYMBOL TABLE

The search of data in the symbol table is also done through the use of pointers, loops and conditional statements. Specifically, three searches are done in the symbol table. The first is to verify that a variable has been declared. The next is to look for the associated class name of a variable used. And finally, to check to see if the variable type matches the operation. These types of checks for data in the symbol table occurs throughout all the conversion functions defined within the *dml_comp.c* file, but are easier to identify in the algorithm found in Appendix K.

E.   THE REAL TIME MONITOR

The specific reason to create the RTM was discussed in Chapter II section C. The functionality of the RTM and the pseudocode developed to pass instructions for data handling and query execution are discussed in Appendix L and [Ref. 5]. There are three parts to the pseudocode that is passed to the RTM and they are the pseudocode, well formed ABDS queries and nearly executable ABDS queries. The pseudocode is simply instructions to the RTM that clarify how operations are to be executed and how they interrelate with other operations, again see Appendix L for specifics. Well formed queries are those that are constructed by the Query constructor and are ready to be executed by the RTM. Nearly executable queries are those that require single or double substitution in order to be executable. These substitutions must be done by the RTM by inserting answers from previous queries.

V. EXECUTION OF A SAMPLE QUERY

In order to demonstrate the complexity of compiling and translating the queries, an example translation involving most of the features of this system follows. The sample translation occurs in three phases, the first being the object oriented query in the newly developed O-ODML see figure. The second phase shows the completed intermediate language table after compilation. Finally, the last phase displays the completed translation with pseudocode, well formed and nearly executable operations.

The O-ODM query, in figure, is one in which the user is attempting to add two courses to a student's schedule. The first two lines of the query declare three variables that will be used in the query, "p" and "i" which are of type object reference and "c" which is of type object set. During compilation these three variables will be entered into the symbol table. The next line of the query is a "find_one" search statement with the class name being that of "Student". The fact that it is a "find_one" and the variable "p" is of type object_ref indicates that only a singular response will be allowed. The following line is a "find_many"

```
Query ChangeStudentSchedule IS
obj_ref  p, i;
obj_set  c;
Begin
p := find_one Student where pname.lname = 'Badgett'
                     and student_no = '20';
c := find_many Course where cse_no = '4114'
                     and sec_no = '1'
                     or cse_no = '3320'
                     and sec_no = '2';
For Each i IN c
  add(p.schedule, i);
End_loop;
End;
```

Figure 5. Sample O-ODML Query

search which includes an "or" as a logical argument. Next is a "for_ loop" which loops once for each member of a given set. Each member of the set is assigned to the same index variable "i" as it enters the loop, therefore each member can than be used in operations within the loop. Inside of the loop an "add" operation is adding each member of the set to the schedule of student "p", one at a time. This is followed by an end of loop statement and an end of query statement.

A.   PHASE 1 - Scanning and Parsing

During this phase the parser calls the scanner and passes it the pointer to the input query file. The scanner reads the characters in the query file until it identifies a token to send to the parser. When the scanner encounters a type declaration of an *obj_ref* or *obj_set* it sets the type flag and once the variable is read in it calls the function *symbtablook()* to add the variable name and variable type in the symbol table. Once the scanner reaches the "Begin" in the query file the symbol table has been completed. The scanner continues to pass tokens to the parser which is attempting to match these tokens to the production rules using a top-down search. Once the parser receives the last token from the scanner either it has returned an "unsuccessfully parsed" with a syntax error or it outputs a "successfully parsed" message and calls the query constructor.

B.   PHASE 2 - Filling in the Intermediate Language Table

Even though the filling in of the intermediate language table is completed during the parsing phase, it can be thought of as a separte phase in the execution of a query. In figure 8 , the compilation of the O-ODM query is broken down into its most atomic form and placed in the intermediate language table. For the most part the intermediate language table is self explanatory and the rules for filling in the table can be found in Appendix D. What may need explanation is the introduction of new variables in the result column and the word "jump" in the operation column. The new variables that were introduced when the parser filled in the table are those starting with t0 and ending with t5. The purpose of these

variables is to allow each line of the table to be treated as the arguments to single simple ABDS operations, as will become evident from examining figure 9. The word jump in the table, indicates a discontinuity in the sequence of execution of the code. Notice that the last entry is not an "End" statement signifying the end of the query as in the O-ODM query. It is not needed since the intermediate language table is stored in a linked list, the fact that the last pointer points to a null value is sufficient to indicate the end of the query.

Line No.	OPERATION	ARGUMENT1	ARGUMENT2	RESULT
0.	find_one	student		p
1.	=	pname.lname	badgett	t0
2.	=	student_no	20	t1
3.	and	t0	t1	0
4.	find_many	course		c
5.	=	cse_no	4114	t0
6.	=	sec_no	1	t1
7.	and	t0	t1	t2
8.	=	cse_no	3320	t3
9.	=	sec_no	2	t4
10.	and	t3	t4	t5
11.	or	t2	t5	0
12.	jump	i	c	
13.	add	p.schedule	i	
14.	end_loop			

Figure 6. Sample Intermediate Language Table

C.   PHASE 3 - Constructing the ABDS Query

The completed product out of the query constructor appears just like the text in figure 6 with the exception that the text is stored in a linked list for ease in reading the data sequentially. (The column of numbers on the right hand side of figure 6 were inserted into the illustration to aid the reader in identifying lines of the pseudocode. These numbers do not actually appear in the pseudocode translation passed to the RTM.) The first two lines are for the declaration of *obj_ref* and *obj_set* variables, respectively. The list of two-letter variables starting with the letter "s" or "r" are those variables created by the query

23

constructor itself, which allow the translation to be a series of simple single argument ABDS operations. The "&" signifies that the return values from the next operation are to be stored in the variable following the symbol. The "~" implies that a single substitution must occur in the next operation prior to the execution of that line. The substitution variable is that variable following the "~". In other words that next line is a nearly executable ABDS line. On line nine, two consecutive lines that read as follows are found, indicating the completion of the "find_one" operation:

&p

*s2, s3

Figure 7. Pseudocode End of O-ODML Find_one Operation

At this point the amount of simple ABDS operations to substitute one O-ODML operation should amplify the power and flexibilty found in the O-ODM. The "find_many" operation is finally answered on lines twenty-four and twenty-five which read as follows:

&c

+s6, s9

Figure 8. Pseudocode End of O-ODML Find_many Operation

The "*" and "+" are set operations which conduct intersection and union of the OIDs stored within the two-letter variables. A for_loop is indicated by "$" followed by a index variable and the obj_set variable "c" on line twenty-six. On the next line a "#" implies a double substitution warning for the following insert statement. This insert statement is preceeded by an "A" to indicate it is an ADD type insert. Finally the "!" signifies the end of the for_loop. The "?" inside the INSERT statement indicates that the RTM must make a call to the OID generator since this operation will be creating a new record. The OID

24

generator exists within the kernal system. Again an "End" statement is not included in the pseudocode for the same reason as the intermediate language table, the peudocode is stored in a linked list.

```
%i,p                                                            (1)

```

Figure 9. Pseudocode Translation of O-ODM Query

VI. CONCLUSIONS

A. ACCOMPLISHMENTS

The primary goal of this thesis research was to design and implement a compiler to translate Object-oriented queries and manipulations into equivalent ABDS queries and manipulations. In order to accomplish this task, several steps needed to be completed. First, a scanner and parser had to be chosen to identify the tokens and check for syntactic and semantic correctness. Additionally, the scanner and parser had to be used for the construction of a symbol table and an intermediate language table respectively. Next a query constructor was created to convert and construct the queries in the pseudocode format which the RTM reads and executes. Finally, documentation was provided to explain all the steps in detail and to assist follow on research, see Appendices A-L.

B. RECOMMENDATIONS FOR FUTURE RESEARCH

Due to the scope of this project several operations were not completely implemented in the query constructor and RTM. The O-ODML operations Insert, Read_input, and Delete were not fully implemented due to the defined need for the user to be interactive with the query constructor or the RTM. The RTM is the logical choice for this interaction since, by the time the RTM begins to execute queries the query constructor is no longer operating. However, the RTM is not able to access the data dictionary or the original query, therefore all instructions concerning the interface must come from the query constructor. Therefore a new protocol must now be added to instruct the RTM to interact with the user and not just the ABDS.

The arithmetic functions of count, min, max, and avg were not included because of the time constraint in completing the project. Again the actual arithmetic operations must occur in the RTM, since the data can only be accessed by the RTM. Likewise, the query constructor must provide the instructions to the RTM for conducting the operations.

27

Also an optimization program can be written to shorten the number of queries entered into the ABDS by combining some of the queries that are logically consecutive and are searching the the same template. This optimization will need to be incorporated in the query constructor once the translation is complete and prior to calling the RTM.

C. SUMMARY

In summary, the O-ODML compiler and interface was constructed and implemented successfully. The inability of the ABDS to search multiple tables simultaneously, pass data between operations and the absence of an "or" operator was overcome by the creation of the RTM. The capability to read a text data dictionary and convert it into the linked list format, in order to use it in aiding the translation of queries, has greatly expanded the capabilities of this model beyond its on data storage in the ABDS. If the data dictionary incorporated in this project is used as the standard for all the models, then the O-ODM will now be able to query any data stored in the ABDS. Though the ABDS may appear limited in its capabilities to serve as the base model for the M^2DBMS it has the ability to operate at the atomic level operations required to support searches, which is what is needed to accomplish the diversity of the M^2DBMS project.

APPENDIX D- RULES TO FILL IN THE INTERMEDIATE TABLE

The following pages illustrate the correct procedure for filling in the intermediate language table. The first line of each example list the Object-oriented operation and its equivalent funtion name in the file "intmed_tabl.c" which contains the actual code to fill in the intermediate language table. The next line of each example lists a generic instance of the Object-oriented operation. That operation is then followed by a conceptual illustration of the intermediate language table. The information in the table shows how the pertinent information from the operation is to be distributed in the columns and rows of the table.

Find_one : [See function "call_find()" in file "intmed_tabl.c"]

$id_a := \text{Find\_one } id_b \text{ where expression}$

Operation	Argument$_1$	Argument$_2$	Result
Find_one	id_b		id_a

APPENDIX J- THE INSTRUCTION MANUAL FOR THE OBJECT-ORIENTED DATA MANIPULATION LANGUAGE COMPILER(OODML)

J.1 Overview

The OODML compiler is based on a scanner produced with the program lex and a parser produced with the program yacc. Lex takes a set of descriptions of possible tokens and produces a C routine, which we call a scanner, that can identify those tokens. Our lex specification "dml_lex.l" contains sixty-five tokens. Yacc takes a concise description of a grammar and produces a C routine, which we call a parser, that can parse that grammar. Both lex and yacc are standard UNIX utilities and we used their original AT&T versions for our compiler.

Since the yacc parser is a higher level routine, it calls the lex scanner whenever it needs a token from the input query. The scanner then reads in the input of characters, until it finds a token of interest to the parser. The scanner only returns a token code.

In our implementation, the scanner does not bother the parser for comments and whitespaces. All the token codes were defined by yacc in order to agree with lex. Token zero signals for the logical end of the input.

We described the actual grammar as a set of production rules. Each rule consists of a single name on the left-hand side of the ":" operator, a list of symbols and action codes on the right-hand side, and a semicolon indicating the end of the rule. Our yacc specification "dml_yacc.y" contains eighty-four production rules. By default, the first rule is the highest-level rule ,i.e., the parser attempts to find a list of tokens which match this initial rule.

In order to fill the intermediate language table, the parser traces specific sequences of tokens in the production rules while it is parsing the query. As soon as the parser has enough tokens to recognize a structure for the intermediate table then it calls the related function declared in "intmed_tabl.c" to perform appropriate action.

After a query is successfully parsed, the execution passes to the function *query_constructor()* declared in "dml_comp.c" to make the necessary conversion for the kernel database.

J.2 Architectural Design

The OODML compiler conceptual model is a context diagram as shown in Figure j.1. The user interface of our system provides two options, either to choose any existing query or to write a new query from the terminal. If the user writes a queryname, the existing query is forwarded to the compiler with the query input file, then the OODML compiler processes the query and outputs either the pseudocode or an error message.
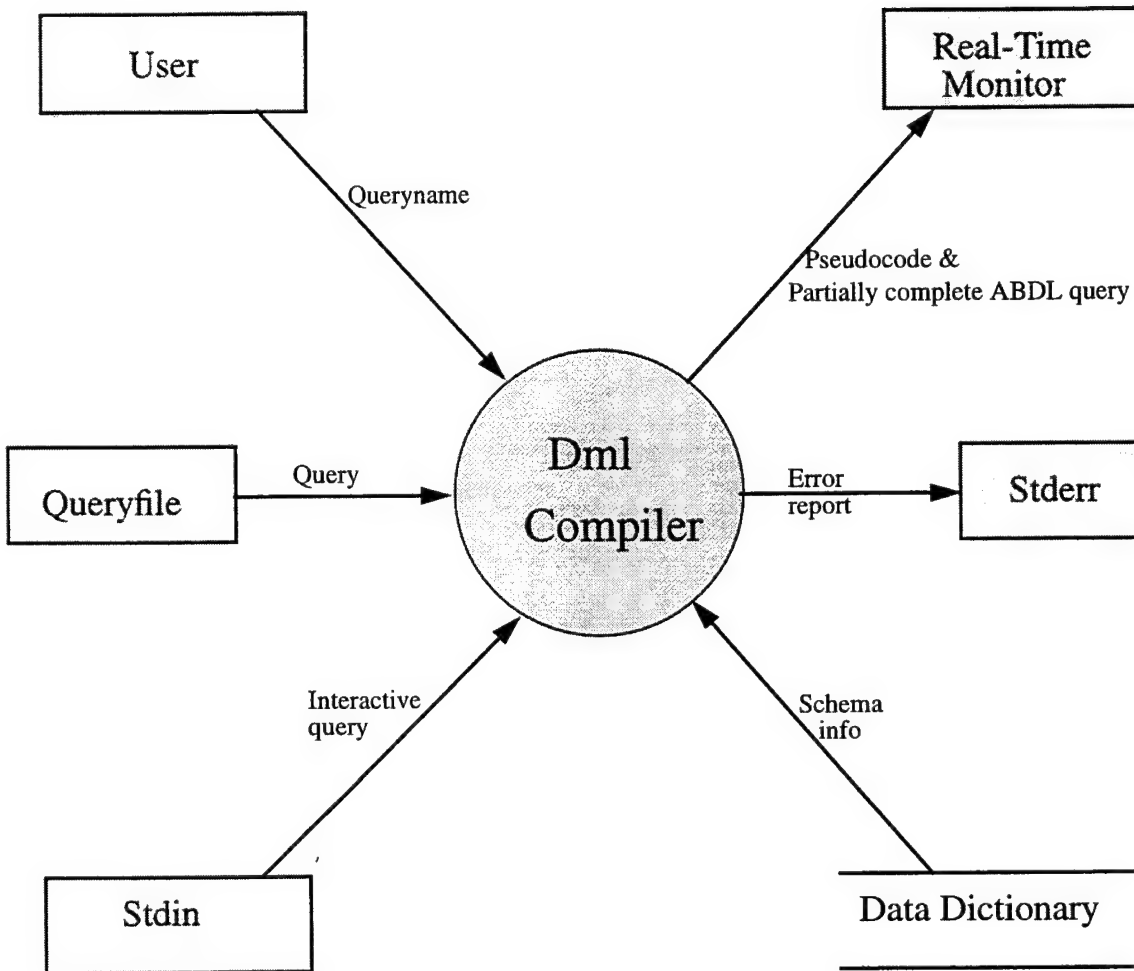

Figure j.1. Top-Level **Dml Compiler** Dataflow Diagram

The detailed elaboration of this context diagram is shown in Figure j.2.
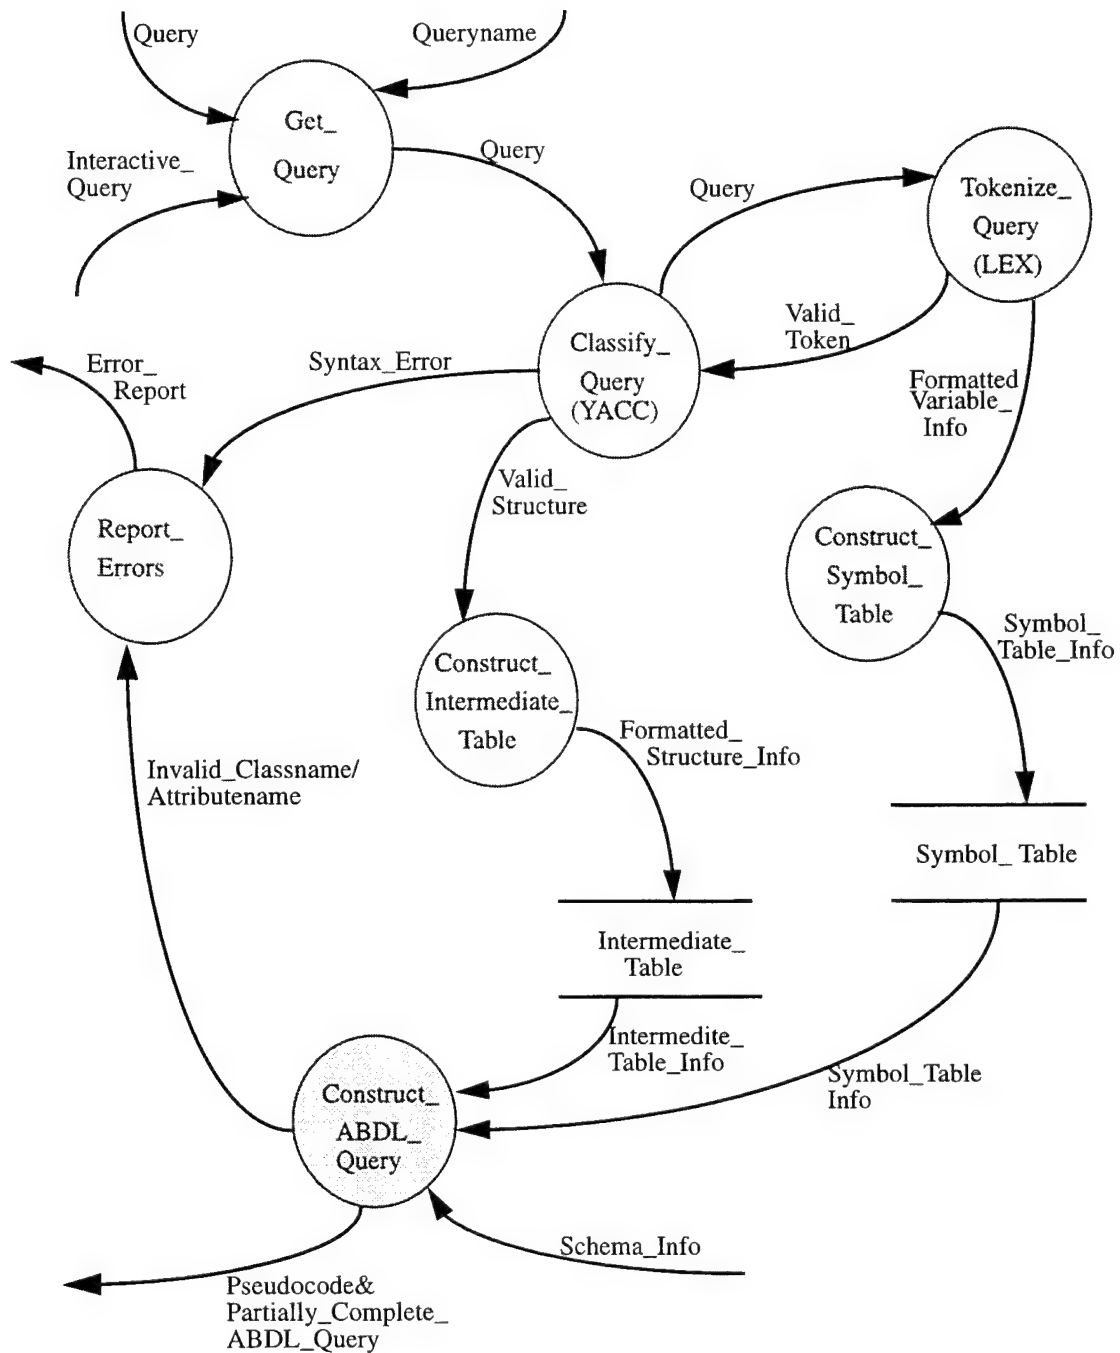

FIGURE j.2. Second-Level **Dml Compiler** Dataflow Diagram

The process "Get_Query" assigns the input queryfile received from the user inter-

face to *dmlin* which is the name of the file the scanner reads, and calls the routine *dml-parse()* which is the parser generated by yacc.

The process "Get_Query" was implemented as the main() and declared in "dml_compiler.c". The parser as a higher level routine calls *dmllex()* which is a scanner generated by lex whenever it needs a token. While the lex scanner is tokenizing each queryline under the supervision of the parser, if it encounters a type declaration then it calls the process "Construct_Symbol_Table", which in turn, fills in the symbol table. The scanner sends all valid tokens to the parser and invalid tokens to the process "Report_Errors". The process "Construct_Symbol_Table" was implemented as a function named *symtablook()* inside the lex specification "dml_lex.l". The parser accepts all valid tokens and tries to match them with the defined grammar rules. While the parser is parsing the query, if it finds a structure of interest to the intermediate table, it calls the process "Construct_Intermediate_Table" with this structure, which in turn, fills in the intermediate table. This process was implemented as a series of functions, one for each structure, inside "intmed_tabl.c". Function prototypes can be found in "intmed_tabl.h". When the parser gets the last token from the scanner, either it will have returned "unsuccessfully parsed" message with the syntax error or it outputs a "successfully parsed" message and calls the process "Construct_ABDL_Query".

"Construct_ABDL_Query" is somewhat the heart of the OODML compiler. This process takes all necessary information from the symbol table, intermediate language table, and data dictionary and constructs the output called the pseudocode and partially complete ABDL query. As shown in figure j.3, it checks the operation code for each structure in the intermediate table and selects the related branch for conversion. The process "Construct_ABDL_Query" was implemented as the main function for the *query_constructor()* and the conversion functions. The function prototypes can be found in "dml_comp.h".

Figure j.4. The KMS Subdirectory Makefile

139

There is no specific function written for the process "Error_Report", but all possible error messages are sent to the *stderr* using the C's *fprintf( )* function.

Since the Object-Oriented Data Definition Language Group also used the UNIX tool *lex* and *yacc* for the OODDL Compiler, we renamed all functions generated by *lex* and *yacc* using UNIX stream editor *sed* to prevent the possible overwrite problem. We created two files "*yy-lsed*" and "*yy-sed*" for renaming the functions with the new prefix "*dml*". After we ran lex and yacc, the following commands edited the generated scanner and parser.

sed -f yy-lsed lex.yy.c > lex.dml.c
sed -f yy-sed y.tab.c > dml.tab.c
sed -f yy-sed y.tab.h > dml.tab.hJ

We put these rules in our "*Makefile*"[see Figure j.4]. So the above commands are executed automatically for each compilation process.

J.3 Incorpation of O-ODML Compiler into the Existing System

The Multi-model/Multi-lingual Database System(M^2DBMS) was designed to support many data languages. In order to support these data languages, the M^2DBMS provides a seperate user interface for each language. All of the user interfaces have identical control flows and structures. As shown in Figure j.5, the overall user interface structure consists of the Language Interface Layer(LIL), Kernel Mapping System(KMS), Kernel Formatting System(KFS), and Kernel Controller(KC) modules.

The LIL routes the user's input query written in the User Data Language(UDL) to KMS. The KMS translates this input query into equivalent Kernel Data Language(KDL) transactions. This process is called the data-language translation. The KMS routes the KDL transactions to the KC which in turn sends the KDL transactions to the Kernel DatabaseSystem(KDS) for execution. The KC routes any answer or response to the KFS for the KDM-to-UDM transformation. Once the transformation is complete, the KFS routes it to the LIL for the final relay to the user in user's data model/language form.
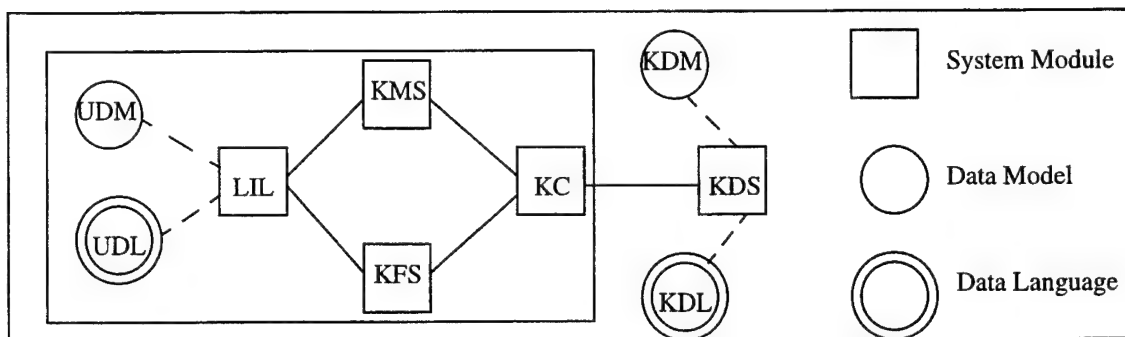

FIGURE j.5 A User Interface of M^{2}DBMS

The actual placement of all O-ODML Compiler component in such a user interface is within the KMS as shown in Figure j.6.

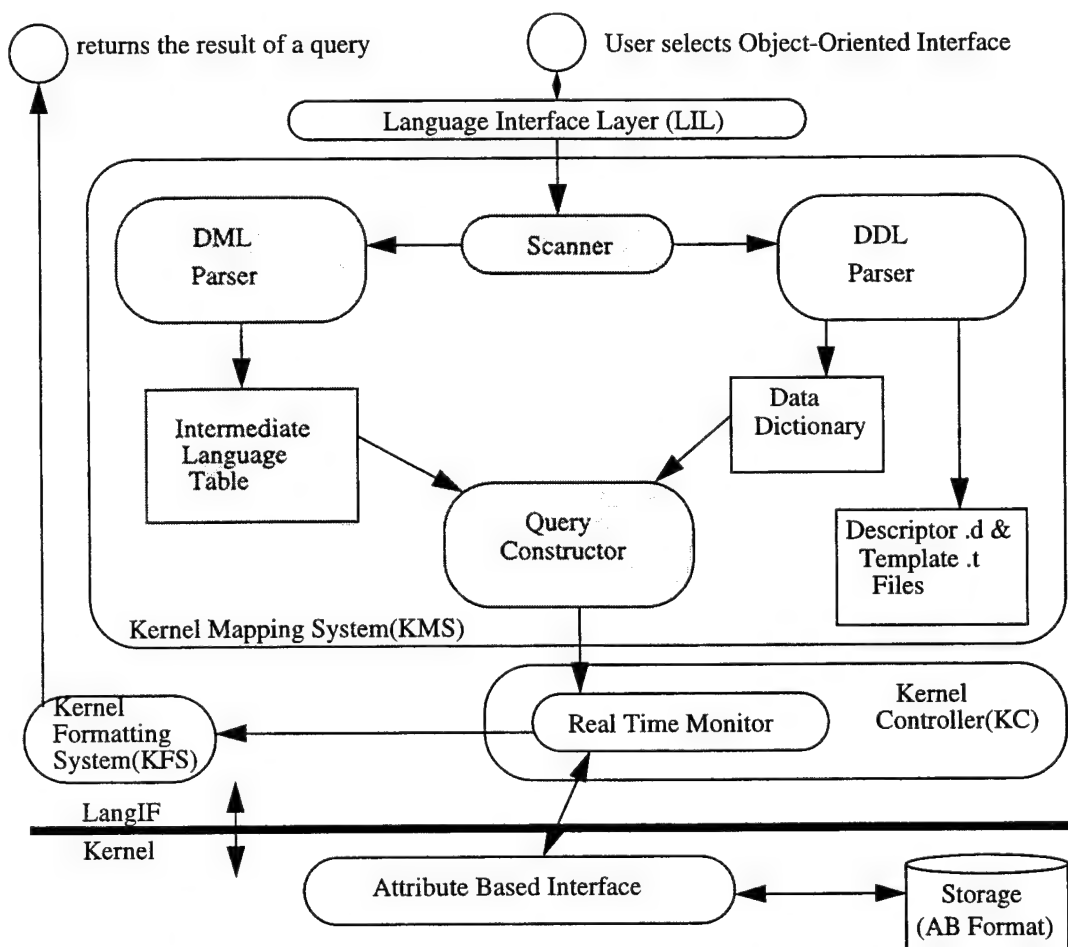

FIGURE j.6 O-ODML Compiler Component Placement

As depicted in Figure j.6, the O-ODML Compiler consists of four subroutines: a scanner, a parser, the intermediate language table construction, and a query constructor.

J.4 Where To Find the OODML Compiler Files

All the C files for OODML Compiler can be found under the directory **greg/CNTRL/TI/langIF/src/Obj/Dml** (See Figure j.7)

Makefile	dml_lex.l	lex.dml.c	yy-lsed
dml.tab.c	dml_yacc.y	intmed_tabl.c	yy-sed
dml.tab.h	dml_compiler.c	dml_comp.c	

FIGURE j.7. Compiler files under the Dml directory

All the header files for function prototypes can be found under the directory **greg/CNTRL/TI/LangIF/include** (See Figure j.8)

dml_comp.h	intmed_tabl.h	symtabl.h

FIGURE j.8. Header files under the Include directory

J.5 How To Modify and Compile the OODML Compiler Files

Since the OODML Compiler is a part of the entire system, whenever a modification is done the whole system needs to be recompiled for a new executable. The System has a general "Makefile" for compiling the entire system. But there is also a specific "Makefile" for the Dml directory. Thus, after a modification in the OODML compiler, a new version can be compiled locally under the same directory. Modification for the header files can be

done under the directory greg/CNTRL/TI/LangIF/include. To compile the entire system:

1. Change the directory to the mdbs/greg/CNTRL(**%cd ../../../../..**)

2. Remove the old executable(**%rm ti.exe**)

3. Change the directory to the mdbs/greg/CNTRL/TI(**%cd TI**)

4. Use Makefile to compile entire system(**%mk**)

5. Check for the compile errors(**%more make_result**)

6. If there is no error then the system is ready to run(**%start**) otherwise fix the error and repeat the step 4 and 5.

Algorithm for Translating the Intermediate Language Table to Executable Pseudocode for the Real Time Monitor

This algorithm covers only the query constructor phase of the DML compiler. The original version was used to break down the problem into solvable units. It had to be updated at the completion of the query constructor to account for changes in the actual algorithm and new problems faced in interfacing with the ABDM.

This algorithm includes some symbology that is not from a programing language or may not be readily understood. Therefore the following explanations are given for clarification:
- On the rule and sub rule title line proceeding the "-" is the name of the corresponding function.
- The "##" is used to indicate a variable definition that is relevant to that function.
- Single quotes are used around variable names while double quotes are used around literals.
- The "*" is used to document limitations of a function.

Rule 1 - Conversion process initiation

tempset - character string that is used for compiler generated variables as they are needed

for single references, when breaking down an O-O query into a series of AB queries.

tempref - character string that is used for compiler generated variables as they are needed

for sets, when breaking down an O-O query into a series of AB queries.

1) Set up declarations of obj_ref and obj_set then place in the symbol table (accomplished by file "dml_lex.l". Additional declarations will be inserted into the symbol table, by the query constructor as needed, and once the query is completely translated the contents of the symbol table will be written to the linked list.

2) Create a linked list data dictionary from the original text version and return the pointer to the new dictionary.

145

3) Get the pointer to the first node (column and row) of the intermediate language table.

4) Read Operation block, if the operation block equals

find_one/find_many	goto rule2	"convert_find_statement()"
jump	goto rule 3	"convert_loop_statement()"
assignment	goto rule 4	"convert_assign_statement()"
display	goto rule 5	"convert_display_statement()"
add	goto rule 7	"convert_add_statement()"

Rule 2 - convert_find_statement()

logical_opar - variable that indicates whether an "and" or "or" is the operator used

r - variable that indicates the type of logical statement (for further information see the function

convert_logical_statement in the file dml_comp.c

1) Set the type classification of the result

A) If this is a find_one query the type of the result must be an obj_ref, else if it is a find_many

the result must be an obj_set. Check to see if the Result block variable (id_a) is of the

correct type:

a) if true, continue

b) if false, Error message such as "type mismatch query construction terminated"

C) Set the result variable of this query to be (id_a) and set its class name to be that of (id_b)

i.e. The final retrieve should produce an OID that identifies a member of the subset indicated

by the class name of variable (id_b)

146

D) Set up a while loop and continue to execute until the result block of the intermediate

language table has a value of 0

E) Set up a branch statement that covers:

logical operators "or"   convert_logical_statement

              "and"   convert_logical_statement

(logical operators must handle precedence also)

contain statement "contains"   convert_logical_statement

relational operators "=,<,>"   convert_relational_statement

F) Go back to the while loop

E) Check the substitution flag variable 'subsflag'

   1) If it has been set then insert the substitution warning and variable node prior to the

      assignment of the current query

   2) If it has not been set then do nothing

G) End of while loop

Rule 3 convert_loop_statement()

1) Check to see if the contents of intmed_ptr -> opar is "jump"

   A) If so, check to see if intmed_ptr -> arg1 and arg2 are in the symbol table and if so

      assign them to the pointers 'symptr1' and 'symptr2' respectively

      a) If either or both do not exist in the symbol table, display an error and exit

   B) The class name of the index variable symptr1 -> clsname gets the class name of

      the range variable symptr2 -> clsname

2) Allocate an abdlque_node

A) Check to see if the contents of intmed_ptr -> opar is "jump"

    a) If so, Stringcopy "$" into 'temptext'

        I) String concatenate intmed_ptr -> arg1 onto 'temptext'

        II) String concatenate "," onto 'temptext'

        III) String concatenate intmed_ptr -> arg2 onto 'temptext'

    b) If not, Stringcopy "!" onto 'temptext'

        I) Add the node to the linked list (following linked list procedures)

Rule 4 Assignment (update)

1) Set the variable "a" equal to zero

2) Stringcopy "oid" into 'temp_oid'

3) Copy the present global variable for arguement1 into 'attr_arr' by breaking arguement1 up at the delimiters "." (see step 3AaII1B in sub rule 5 convert_contains_statement for a step by step break down of this algo)

4) Take the tokenized results of step 3 ('path_expr[0])' and check to see if it is in the symbol table and if so, assign the pointer 'symptr' to it

A) Set the variable "s" equal to zero and the variable 'rf' equal to one

B) Stringcopy symptr -> clsname into 'reftabl_arr[s]'

C) Use a do while loop, (condition at the bottom of loop first entry mandatory)

    a) Check to see if 'reftabl_arr[s]' is in the data dictionary

        I) Check to see if the 'path_expr[rf]' is in the current class and if so assign the pointer 'attr_ptr' to it

            1) If so, check to see if the contents of attr_ptr -> dict_ref_type is the empty string

148

A) If so, then call construct_update() and break

2) Else, check to see if the contents of attr_ptr -> dict_ref_type is the string "ref"

A) If so, set the 'subsflag' equal to one

B) Call construct_retrieve_by()

C) Increment the 'rf' variable

D) Use a do while loop, (condition at the bottom of loop first entry mandatory)

I) Stringcopy attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

II) Check to see if 'reftabl_arr[s]' is in the data dictionary

1) Check to see if the 'path_expr[rf]' is in the current class and if so assign the

pointer 'attr_ptr' to it

A) If so, check to see if the contents of attr_ptr -> dict_ref_type is the empty

string

a) If so, then call construct_update() and break (This break gets you out

of the inner loop)

B) Else, check to see if the contents of attr_ptr -> dict_ref_type is the string

"ref"

a) If so, set the 'subsflag' equal to one

b) Call construct_retrieve_by()

c) Increment the 'rf' variable

C) Else, check the current class for inherit {using the check_inherit()} and

if so, assign the pointer attr_ptr to it

E) End of inner do while loop, condition is that attr_ptr must exist

3) Break, (This break gets you out of the outer loop)

II) Else, check the current class for inherit {using the check_inherit()} and if so, assign the pointer 'attr_ptr' to it

    1) Stringcopy attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

D) End of outer do while loop, condition is that 'attr_ptr' must exist

Rule 5 convert_display_statement()

* note - This function has a limitation of six arguments.

1) Stringcopy "oid" into the string 'attrname'

2) Set the value of the variable 'b' equal to zero

3) Use a while loop with the condition that the contents of intmed_ptr -> opar equal the string "display"

    A) Set the value of variables 'a' and 'k' equal to zero

    B) Copy the present global variable for arguement1('arg1') into 'display_arr' by breaking up arguement1 at the delimiters "." (See step 3AaII1B, in sub rule 5 convert_contains_statement() for a step by step break down of this algo)

    C) Check to see if intmed_ptr -> arg2 exists

        a) If so, increment the variable 'b'

        b) Set the value of the variables 'a' and 'k' equal to zero

        c) Copy the present global variable for arguement1('arg1') into 'display_arr' by breaking up arguement1 at the delimiters "." (See step 3AaII1B, in sub rule 5 convert_contains_statement() for a step by step break down of this algo)

    D) Increment the variable 'b'

    E) Check to see if the contents of intmed_ptr -> result equals one

A) If so, now move the intmed_ptr to the next node

F) Else, break

4) Set the value of the variable 's' equal to zero

5) Set the value of the variable 'subsflag' equal to zero

6) Check to see if the tokenized variables 'display_arr' are in the symbol table and if so copy the classname into 'reftabl_arr', else display an error

7) Set the value of the variable 'rf' equal to one

8) Use a do while loop, (condition at the bottom of loop first entry mandatory)

    A) Check to see if 'reftabl_arr[s]' is in the data dictionary

        a) If so, Check to see if the 'display_arr[i][rf]' is in the current class and if so assign the pointer 'attr_ptr' to it

        I) If so, check to see if the contents of attr_ptr -> dict_ref_type is the empty string

            1) IF so, Stringcopy the contents of 'display_arr[i][rf]' into 'first_attr'

                A) Stringcopy the contents of 'first_attr' into 'attrlist'

                B) Set up a for loop to check and see if the following arguments are in the same table ('u' is the index variable and is initially set at i+1, loop until u<b

                a) Check to see if the 'display_arr[u][rf]' is in the current class and if so assign the pointer 'attr_temp' to it

                I) If so, check to see if the contents of attr_temp -> dict_ref_type is the empty string (Yes answer means that the following attribute is in the same table)

                    1) If so, String concatenate "," into 'attrlist'

                        A) String concatenate the contents of 'display_arr[u][rf]' into 'attrlist'

                        B) Increment the variable 'i'

2) Else, Break (not in the same table)

C) Call construct_retrieve_display()

D) Break

2) Else, check to see if the contents of attr_ptr -> dict_ref_type is "ref"

A) If so, set the 'subsflag' variable equal to one

a) Call construct_retrieve_by()

b) Increment the variable 'rf'

c) Use a do while loop, (condition at the bottom of loop first entry mandatory)

I) Stringcopy the value of attr_ptr -> dict_ref_type into 'reftabl_arr[s]'

II) Check to see if 'reftabl_arr[s]' is in the data dictionary

1) Check to see if the 'display_arr[i][rf]' is in the current class and if so assign the pointer 'attr_ptr' to it

A) If so, check to see if the contents of attr_ptr -> dict_ref_type is the empty string

a) IF so, Stringcopy the contents of 'display_arr[i][rf]' into 'first_attr'

I) Stringcopy the contents of 'first_attr' into 'attrlist'

II) Set up a for loop to check and see if the following arguments are in the same table ('u' is the index variable and is initially set at i+1, loop until u<b)

1) Check to see if there presently exists an attribute and that it and the previous attribute have the same path expression

A) If so, assign the pointer 'attr_temp' to 'display_arr[u][rf]'

a) Check to see if the contents of attr_temp -> dict_ref_type

is the empty string

I) If so, String concatenate "," onto 'attrlist'

1) String concatenate 'display_arr[u][rf]' onto 'attrlist'

2) Increment the variable 'i'

II) Else, Break (path expression not the same)

B) Else, Break (current attribute is not in the same table

III) Call construct_retrieve_display()

IV) Break (found primitive value and called construct)

b) Break (gets out of do loop when primitive value found

B) Else, check to see if the contents of attr_ptr -> dict_ref_type is "ref"

a) If so, set the 'subsflag' variable equal to one

I) Call construct_retrieve_by()

II) Increment the variable 'rf'

C) Else, check inherit for the second attribute (The second attribute

was not in the table) and assign it to the pointer 'attr_ptr'

d) End of while loop if the 'attr_ptr' exist loop back up

3) Else, check inherit for the second attribute (The second attribute was not in the

table) and assign it to the pointer 'attr_ptr

A) If so, Stringcopy attr_ptr -> dict_ref_table into reftabl_arr[s]

9) End of while loop if the attr_ptr exist loop back up

Rule 6 add convert_add_statement()

1) Set the variable 'a' equal to zero

2) Copy the present global variable for arguement1 into 'path_expr[a][k]' by breaking

arguement1 up at the delimiters "." (see step 3AaII1B in sub rule 5 convert_contains_statement

for a step by step break down of this algo)

3) Take the tokenized results of step 3 ('path_expr[0])' and check to see if it is in the symbol table

and if so, assign the pointer 'symptr' to it

4) Set the variable 's' equal to zero

5) Stringcopy symptr -> clsname into 'reftabl_arr[s]'

6) Check to see if 'reftabl_arr[s]' is in the data dictionary

    A) Check to see if 'a' is greater than zero (if so it is a store add)

        a) Check to see if the 'path_expr[1]' is in the current class and if so assign the pointer

          'attr_ptr' to it

          I) If so, check to see if the contents of intmed_ptr -> arg2 are in the symbol table and

            assign it to the pointer 'symptr'

            1) If so, increment the variable 's'

                A) Stringcopy attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

                B) Check to see if 'reftabl_arr[s]' is in the data dictionary

                    a) If so, Call construct_add()

    B) Else, check the current class for cover {using the check_cover()} and if so, assign the

        pointer 'attr_ptr' to it

        a) Increment the variable 's'

          I) Stringcopy attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

          II) Check to see if the contents of intmed_ptr -> arg2 are in the symbol table and

            assign it to the pointer 'symptr'

1) If not error

2) Else, (if so)

    A) Check to see if 'reftabl_arr[s]' is in the data dictionary

        a) If so, Call construct_add()

Sub Rule 1 - convert_rel_expr()

1) Initialize the a temporary array ('attr_arr[]') to an empty array

2) Copy the present global variable for arguement1('arg1') into 'attr_arr[]' by breaking up arguement1 at the delimiters "." (See step 3AaII1B, in sub rule 5 convert_contains_statement() for a step by step break down of this algo)

3) Check to see if the current path expression for this class is in the data dictionary and set the pointer on this class

    A) If so, check to see if the current attribute 'attr_arr' is in the class and set the 'attr_ptr' to point to this attribute column of the class

        a) If so, check to see if the 'dict_ref_type' column is empty

            I) If so, check to see if argument 2 is in the symbol table

                1) If so, set the substitution flag equal to one

                2) Call construct_retrieve_gen()

                3) Return the 'objset_arr[p-1]'

        b) Else, check to see if the 'dict_ref_type' column contains the key word "ref"

            I) If so, increment the 's' and 'a' variable counters

            II) String copy the value of attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

            III) String copy the value of construct_retreive_ref() into the variable 'tempvar'

IV) Decrement the 's' and 'a' variable counters

V) Set the substitution flag equal to one

VI) Call construct_retrieve_gen()

VII) Return the 'objset_arr[p-1]'

B) If 'attr_arr' is not in the class check all the 'dict_ref_type' column for all the attributes in

that class and return the attribute pointer to the attribute row with an "inherit"

{check_inherit()}

a) Initialize the inheritance counter to zero

b) While the attr_ptr = check_inherit() LOOP

I) Increment the 'inherit_cnt' and the 's' variables

II) String copy the value of attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

III) Check to see if the path expression for the class name in 'reftabl_arr[s]' is in the data

dictionary

1) If so, check to see if the current attribute 'attr_arr' is in the class and set the

'attr_ptr' to point to this attribute column of the class

A) If so, check to see if the 'dict_ref_type' column is empty

a) If so, Call construct_retrieve_gen()

b) String copy an empty string into 'reftabl_arr[s]'

c) 's' gets the value of 's' minus the value of 'inherit_cnt'

B) If so, and the 'dict_ref_type' column contains "ref" then

a) Increment the 's' variable

b) String copy attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

c) Increment the 'a' variable

d) String copy the char * returned from construct_retrieve_ref() {by calling

construct_retrieve_ref() inside of a strcpy} into 'tem_val'

e) String copy an empty string into 'reftabl_arr[s]'

f) Decrement 's' and 'a' variables

g) Set the value of 'subsflag' equal to one

h) Call construct_retrieve_gen()

i) 's' gets the value of 's' minus the value of 'inherit_cnt'

j) Return the 'objset_arr[p-1]'

C) Else, 'attr_ptr[0]' is not a valid attribute name

4) Else, 'reftabl_arr[s]' does not exist in the dictionary

Sub Rule 2 convert_logical_statement()

1) Initialize the 'left' and 'right' variables to zero

2) Decrement the index (variable 'r' from convert_find_statement)

3) Branch to the correct case statement according to the index value

4) Call construct_retrieve_logical() with the new values of 'left' and 'right'

Sub Rule 3 - construct_retrieve_ref()

1) Check to see if the path expression for the class name in 'reftabl_arr[s]" is in the data dictionary

A) If so, check to see if the current attribute 'attr_arr' is in the class and set the 'attr_ptr' to

point to this attribute column of the class

a) If so, check to see if the 'dict_ref_type' column is empty

157

I) If so, Call construct_retrieve_gen()

II) Return the 'objset_arr[p-1]'

b) If so, and the dict_ref_type column contains "ref" then

I) Increment the 's' and 'a' variables

II) String copy attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

III) String copy the char * returned from construct_retrieve_ref() {by calling

construct_retrieve_ref() inside of a strcpy} into 'tem_var'

IV) Decrement the 's' and 'a' variables

V) Set the value of 'subsflag' equal to 1

VI) Call construct_retrieve_gen()

VII) Return the 'objset_arr[p-1]'

c) If 'attr_arr' is not in the class check all the dict_ref_type column for all the attributes in

that class and return the attribute pointer to the attribute row with an "inherit"

{check_inherit()}

I) Increment the 's' variable

II) String copy attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

III) String copy the char * returned from construct_retrieve_ref() {by calling

construct_retrieve_ref() inside of a strcpy} into 'tem_var'

IV) Decrement the 's' variable

V) Return 'temp_var'

Sub Rule 4 construct_retrieve_gen()

temptext - string used to store the text of a query (the string is a member of the struct/node)

ref_temp - string used solely to store and manipulate strings prior to concatenation onto temptext

1) Allocate an abdlque_node

2) Stringcopy an "&" into string 'temptext'

3) String concatenate arg1 onto 'temptext' and copy 'temptext' in abdlque_current_node->text

4) Add the node to the linked list (following linked list procedures)

5) If 'subsflag' is greater than 0 than

    A) Allocate an abdlque_node

    B) Stringcopy a "~" into string 'temptext'

    C) String concatenate arg2 onto 'temptext' and copy 'temptext' in

       abdlque_current_node -> text

    D) Add the node to the linked list (following linked list procedures)

6) Allocate an abdlque_node

7) Stringcopy a "[RETRIEVE ((TEMP =" into string 'temptext'

8) Stringcopy a "reftabl" into string 'ref_temp'

9) String concatenate the results from function call convertoclassname(ref_temp) onto 'temptext'

10) String concatenate ") and (" onto 'temptext'

11) Stringcopy a 'attrname' into string 'ref_temp'

12) String concatenate the results from function call convertoupper(ref_temp) onto 'temptext'

13) String concatenate 'relexpr' onto 'temptext'

14) String concatenate arg2 onto 'temptext'

15) String concatenate "))(OID)] onto 'temptext' and copy 'temptext' in

    abdlque_current_node->text

16) Add the node to the linked list (following linked list procedures)

<u>Sub rule 5 convert_contains_statement()</u>

1) Check to see if arg1 is the string "it"

    A) If so, Check to see if the path expression for the class name in 'reftabl_arr[0]' is in the data dictionary

        a) If so, let 'attr_ptr' point to the attribute which is of relationship type "cover"

            I) Increment the variable 's'

            II) Stringcopy the contents of attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

            IV) Check to see if the path expression for the class name in 'reftabl_arr[s]' is in the data dictionary

                1) If so, Stringcopy "oid_" onto string 'temp1'

                2) Check to see if intmed_ptr -> arg2 is in the symbol table and assign it to the pointer 'symtab_ptr'

                    A) If NOT, then output a message "undeclared variable"

                    B) If So, String concatenate "symtab_ptr -> clsname" into string 'temp1'

                    C) Check to see if 'temp1' is in the present class and assign its attribute pointer to 'attr_ptr'

                        a) If so, Stringcopy "OID_" onto string 'temp2'

                        b) Stringcopy 'reftabl_arr[s-1]' onto string 'temptext'

                        c) String concatenate the result of the converttoupper(temptext) onto the string 'temp2'

                        d) Call convertoupper(temp1) to insure correct format

e) Set the value of 'subsflag' equal to one

f) Call construct_retrieve_by()

g) Set the value of 'logopar' equal to two

h) Call construct_retrieve_logical()

i) Stringcopy an empty string into 'reftabl_arr[s]'

j) Decrement the variable 's'

k) Set the 'subsflag' equal to 0

l) Return the 'objset_arr[p-1]'

2) Check to see if 'arg2' is the string "it"

A) **** This type of covering will be implemented by follow on groups ****

3) Else, String copy the contents of intmed_ptr -> arg1 into the array 'attr_arr[0]'

A) Check to see if 'reftabl_arr[s]' is in the data dictionary and if so set the pointer

a) If so, check to see if 'attr_arr[0]' is in the present class, if so set the pointer 'attr_ptr' the attribute

I) Check to see if the contents of attr_ptr -> dict_attr_type is "set_of"

1) If so, increment the 's' variable

2) Stringcopy the contents of attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

3) Check to see if the contents of 'reftabl_arr[s]' is in the data dictionary

A) If so, stringcopy "oid_" into 'temp1'

B) Check to see if the contents of intmed_ptr -> arg2 is in the symbol table, if so then have the pointer 'symtab_ptr' point at it

a) If so, string concatenate the contents of symtab_ptr -> clsname onto 'temp1'

b) Check to see if the concatenated contents of 'temp1' is one of the hidden

161

attributes in the class, and if so, have the pointer 'attr_ptr' point to it

I) If so, stringcopy "OID_" into the string 'temp2'

II) Stringcopy the contents of 'reftabl_arr[s-1]' into 'temptext'

III) Convert the contents of 'temptext' to upper case (converttouppper) and
string concatenate it onto 'temp2'

IV) Convert the contents of 'temp1' to upper case (converttouppper)

V) Set the substitution flag equal to one

VI) Call construct_retrieve_by()

VII) Stringcopy an empty string into 'reftabl_arr[s]'

VIII) Decrement the 's' variable

IX) Return 'objset_arr[p-1]'

II) Check to see if the contents of attr_ptr -> dict_attr_type is "inverse_of"

  1) If so, set the variables 'k' and 'l' equal to zero

    A) Find the string length of attr_ptr -> dict_ref_table and set the variable length
equal to it

    B) Use a for loop to count from 0 to length(i) LOOP (Used to tokenize attribute
names

      a) Check to see if the value of attr_ptr -> dict_ref_table[i] is "."

        I) If so, 'settype_arr[k][l]' gets the value "\0" (end of string)

          1) increment the variable 'k'

          2) Set the value of the variable 'l' equal to zero

        II) If not, 'settype_arr[k][l]' gets the value of attr_ptr -> dict_ref_table[i]

      b) 'settype_arr[k][l]' gets the value "\0" (end of string)

4) Check to see if 'settype_arr[0]' is in the data dictionary

   A) If so, check to see if 'settype_arr[1]' is in the current class and if so set the pointer

      'attr_ptr' to point at it

      a) Increment the variable 's'

      b) Stringcopy the contents of attr_ptr -> dict_ref_table into 'reftabl_arr[s]'

      c) Check to see if 'reftabl_arr[s]' is in the data dictionary

        I) If so, Stringcopy "oid_" into 'temp1'

        II) Check to see if intmed_ptr -> arg2 is in the symbol table and if so assign the pointer

           'symtab_ptr' to it (error message are appropriate here if not)

           1) If so, string concatenate the contents of symtab_ptr -> clsname onto 'temp1'

           2) Check to see if the contents of 'temp1' is in the current class and if so assign the

              pointer to it

              A) If so, stringcopy "OID_" into 'temp2'

              B) Stringcopy the contents of 'reftabl_arr[s-1]' into 'temptext'

              C) Convert the contents of 'temptext' to uppercase and concatenate the results to

                 'temp2'

              D) Convert the contents of 'temp1' to uppercase

              E) Set the value of the substitution to one

              F) Call Construct_retrieve_by()

              G) Stringcopy an empty string into 'reftabl_arr[s]'

              H) Decrement the variable 's'

              I) Return 'obset_arr[p-1]'

21) String concatenate "," onto 'temptext'

22) Check to see if the contents of arg1_cls_name is equal to the contents of

dict_att_temp -> dict_ref_table

A) If so, string concatenate 'attr_arg1' onto 'temptext'

B) Else, tring concatenate 'attr_arg2' onto 'temptext'

23) String concatenate ">)]" onto 'temptext' and copy 'temptext' in abdlque_current_node->text

24) Add the node to the linked list (following linked list procedures)

APPENDIX L- DML TO RTM PSEUDOCODE

This document describes the pseudocode developed to assist the RTM in processing queries.

Declarations:

The declaration of variables in the Real time monitor pseudocode will be accomplished by using the symbols '%' and '@'.

obj_ref : %   obj_ref a   : % a
obj_set : @   obj_set b,c,d : @ b,c,d

Assignment:

Assignments in the Real time monitor pseudocode will be accomplished by using the '&' followed by the desired variable that is to accept the assignment. No other entries on that line. The next line will then have to be one of the five Attribute based functions.

:=   : &   a := find_One..... :   &a
                                             RETRIEVE [(......)(OID)]

For Loop:

For loops are handled by using the '$' followed by the index variable (must of type obj_ref) a comma then the set variable (must be an obj_ref).

For Each i in b   : $ a, b
.....   DELETE (TEMP=student) (OID=a)
End_Loop; $

End For Loop :

For loops are ended by using "!" by itself.

.....   DELETE (TEMP=student) (OID=a)
End_Loop;   !

Cross Product:

Cross products are included in the pseudocode to accommodate for the lack of functionality in the retrieve common provided in the ABDM. The cross product (or more correctly stated equijoin) symbol is '*' and is followed by two variables containing the sets to be joined.

&b
[RETRIEVE(TEMP=Name)(lname=Jones)(OID)]

&c
[RETRIEVE(TEMP=address)(city=monterey)(OID)]
&d
* b,c

Union :
Or is accomplished by using "+" followed by the variables to be unioned (separated by a comma)

+ sb, sc

Substitution Warning:
In order to simplify the job of the real time monitor a method was developed to indicate that a substitution is required in the next line of the ABDL query and what variable was to be involved. The '~' followed by the variable to be substituted in the next line, is how this is accomplished.

~ p, pa

Double Substitution Warning:
This fills the same requirements of the substitution warning with the exception that two variables will be substituted instead of only one. This occurs only in the ADD and Delete operations due to the manner in which sets are stored in the ABDM. The '#' followed by the variables to be substituted in the next line, is how this is accomplished.

sa,sb

Get Common Warning:
This fills nearly the same requirements of the cross product but is specifically used with the cover relationship. The '^' followed by the variables to be used in the next line, is how this is accomplished. Moreover the constraints on this is that the first argument must be of type object set while the second arguement may be either an object set or object reference.

^ sa, sb
